# Preface

This is the first edition of Alaska Population Projections, a new annual publication of the Alaska Department of Labor. It is designed to provide frequently requested information about the possible future population of Alaska. Special thanks goes to Signe Wetrogan of the U.S. Census Bureau for her aid with data and methodological questions.

Any persons wishing further information concerning these projections or methods should contact: Greg Williams, State Demographer (907) 465-4500.

Persons desiring additional copies or persons wishing to be added to our mailing list for this publication should write:

# Part 1: Methodology, Assumptions, and Trends

## INTRODUCTION

This report presents estimates and projections for the State of Alaska by age and by sex. A revised estimates series for July 1, 1981 through July 1, 1984, is presented along with provisional estimates for July 1, 1985 and projections for July 1, 1986 through July 1, 1991.

An estimate is distinguished from a projection in that current data indicative of population change are available for the year of an estimate, while they are not available for a projection year. Typically, estimates are lagged one year because it takes at least 6-12 months for indicator series to be gathered, checked for errors, and used in estimating models. Statistics for the current year, therefore, must almost always be a projection of recent trends.

The current estimates do not agree with those published by the U.S. Census Bureau in their P-26 State Population Estimates. The difference is primarily because U.S. Census Bureau estimates for the 1980s are not corrected for the level of undercount experienced in Alaska, while the Alaska Department of Labor's are corrected for an estimated undercount of approximately 3.6%. This undercount agrees closely with the unpublished post enumeration program estimates of undercount independently produced by the U.S. Census Bureau. Nationwide the undercount was on average 1.0% in 1980.

This edition is composed of two sections. Part 1 discusses the general methodology, assumptions, and results of these projections. Part 2 presents the detailed tables of estimates and the sets of projections based upon the varying assumptions discussed in Part 1.

During the remainder of the 1980's decade, we intend to annually update and expand the coverage of these projections depending on the resources available. Each new projections series will continue to reflect current methodological improvements and data changes for the purpose of improving these projections. These projections supersede any previously published by the Alaska Department of Labor.

*Projections are probability statements of the population which would result if a series of assumptions concerning birth, death and migration are met during the coming years. Whether demographic or economic, relationships used in any set of projections are based upon known historical relationships of the variables involved. No one making projections has a crystal ball which will accurately predict the future. This is particularly true of the economic and historic events which will influence migration patterns. Rapid shifts in economic conditions are typical of Alaska and unique events have played a major role in shaping it's history. As a result, these projections present a logical range within which it is reasonable to assume that events may occur based upon recent past expereince. These and all other projections assume that no major natural or man-made disaster will occur during the projection period.*

**Table 1.1 Principle Fertility and Mortality Assumptions**

| Subject | Low Assumption | Middle Assumption | High Assumption |
|---|---|---|---|
| Ultimate U.S. lifetime births per woman 2050..... | 1.6 | 1.9 | 2.3 |
| Ultimate Alaska lifetime births per woman 2050..... | 2.1 | 2.4 | 2.9 |
| U.S. life expectancy at birth: | | | |
| 1980 Male..... | | 70.0 | |
| 1980 Female..... | | 77.5 | |

| 2005 Female..... | 82.0 | 80.1 | 78.4 |

Source for U.S. fertility and mortality assumptions: Current Population Reports, Series P-25, No. 952.

These projections present a low, middle, and high projected population. The middle series represents the "most likely" scenario for future state growth as judged from mid 1986. The presentation of population figures in unrounded form does not mean that they are accurate to the last digit. Statistics are presented in an unrounded form to allow the data to match the total without distortion of the specific numbers. Estimated and projected numbers should be rounded to the nearest 100 when used for other purposes.

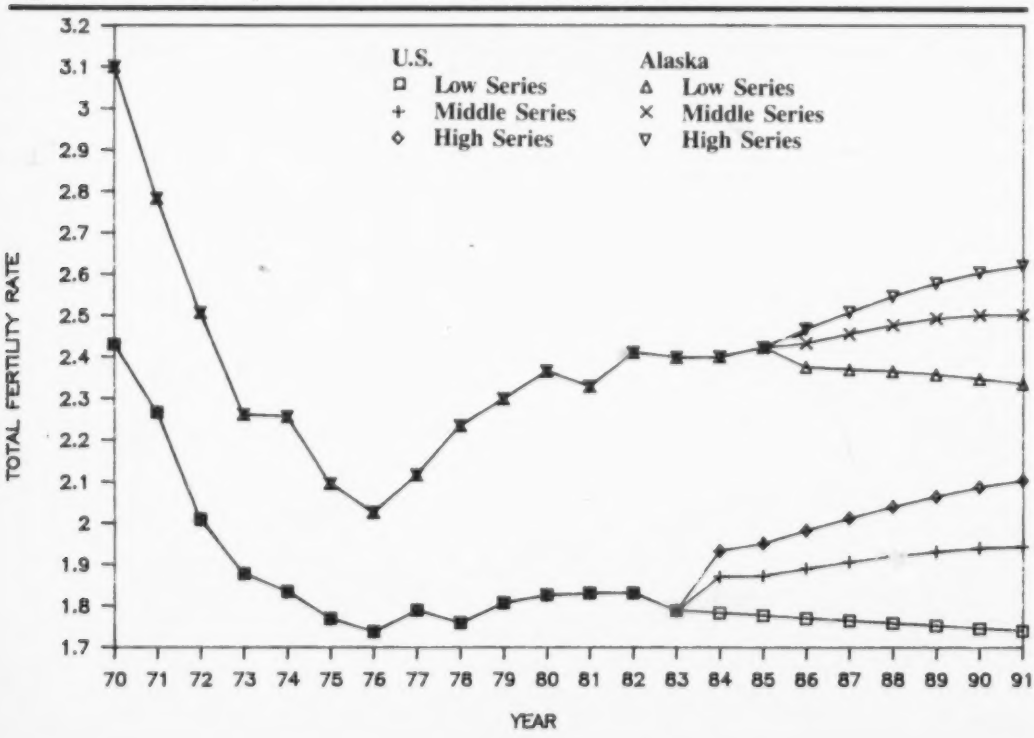
The high and low series represent the population which would exist if the extremes of demographic events were to cumulatively occur throughout the projection period. They represent the logical extremes of the projection above and below which we would not expect the population to go.

There are several principles of projection which the reader should keep clearly in mind in using these or any projections. The smaller the component projected, the greater the probability of error. Thus projections for small age/sex groups are more subject to error than larger ones. Secondly, populations experiencing unstable or rapid growth are subject to more projection error than stable populations. Thus a projection of the number of persons in their early 20s is more difficult to predict than the population over 65 because persons in their 20s are an age group that is especially subject to the changing conditions which affect migration rates. Because of these conditions, projections must be updated frequently in order to incorporate the latest conditions. Annual updates of these projections will reflect current trends and information which may affect the projected growth of the state.

The projections series are based on the July 1, 1985 population estimates and are projected forward using alternative assumptions for future fertility, mortality and migration levels. Single year of age information is shown for selected ages and five year age groups. There are a total of 81 possible series representing each possible combination of high, middle, and low assumptions series for fertility, mortality, migration to Alaska and migration from Alaska.

Throughout this report, Alaska population projections are compared with the most recent set of national population projections. All U.S. trends discussed here, as well as national assumptions of fertility and mortality are described in detail in the following publication: Gregory Spencer, *Projections of the Population of the United States by Age, Sex and Race: 1983 to 2080*, Current Population Reports, Population Estimates and Projections, Series P-25, No. 952, May 1984.

**Figure 1.1 Total Fertility Rates for Alaska and the U.S., 1970-1991**



## ESTIMATES AND PROJECTIONS MODEL

These estimates and projections use a modified form of the traditional cohort-component model in which the components of population change (births, deaths, and migration to and from Alaska) are projected separately for each birth cohort (persons born in each year).

The basic demographic equation used is as follows:

Population P2 = Population P1
[+ Natural Increase (Births - Deaths)]
[+ Net Migration (Out Migration to Alaska—Out Migration from Alaska)]
Where: P1 = Beginning Population
P2 = End Population

### Estimates

The July 1, 1980, base population has been adjusted for estimated undercount and is carried forward year by year to 1985 by adding known births and deaths derived from Alaska vital statistics as provided by the Planning Division of the Alaska Department of Health and Social Services. These statistics have been corrected for unknown characteristics. Migration to and from the state for the estimate period was derived from a combination of 1980 U.S.Census data and U.S. Internal Revenue Service statistics on migration. For the period 1980-1985, the model was calibrated using public and private school enrollments for grades 1-8 against the population 6-14 and medicare data was compared against persons 65+. Comparisons were also made to the year of birth statistics from the Alaska Permanent Fund. The model predicted the age structure of permanent fund applicants quite well five years from the base year. The model also allows an estimate of those persons (primarily military and dependents) who were not applicants. While the overall relationship of the age of persons who apply for the permanent fund is reasonably stable from year to year, the overall proportion of Alaska's population applying has varied from year to year. Trends in dividend applicants are a relatively poor predictor of trends in the state's population growth.

### Projections

The form of cohort component projection model developed for these projections implements many aspects of the most current developments in demographic models. This type of projection model is known as a Multiregional Demographic Model, and it reflects developments recently made by Andrei Rogers and others.[1] This type of model will be used in the forthcoming U.S. Census Bureau projections for states. While the general model used is similar to a multiregional demographic model, the specific modified model used here was developed in the Alaska Department of Labor and to our knowledge is the first application at the state level. Multiregional demographic models differ from traditional cohort component projection models in that they use multiple decrement life table techniques to model a series of interacting demographic events, each of which has a schedule of probabilities of occurrence. For example, in a normal life table model, the schedule of probabilities reflect the chances of living from one given age to the next. In addition to life table survival, the model incorporates age/sex specific probabilities that women of child bearing age will give birth, and probabilities of people moving out of Alaska. It also incorporates probabilities that people will move out of the "balance of the U.S." to Alaska. In each case, there is a population "at risk" of experiencing a series of demographic events.

From 1985 through 1991 the model uses projected life table survival rates. Life table probabilities for migration to and from Alaska were also developed both by single year of age and by sex, and they are currently being extended to include projections of white and Alaska Native migration. These latter, however, were not available in time for this publication. Each year a new birth cohort of persons under age 1 is added to the population by applying projected mid year age-specific fertility rates to the July 1st female population for the prior year.

[1] See for example Andrei Rogers, *Introduction to Multiregional Methematical Demography*, Wiley 1975 or Kenneth C. Land and Andrei Rogers *Multiregional Mathematical Demography*, Academic Press, 1982.

**Table 1.2 Total Alaska Females - Estimates and Projections of Total Fertility Rates and Fertility Rates by Age: Selected Years, 1970 to 2050**

| SERIES AND CALANDAR YEAR | TOTAL FERTILITY RATE | AGE SPECIFIC FERTILITY RATES (LIVE BIRTHS PER 1000 WOMEN) | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|

## ASSUMPTIONS

Table 1.1 shows high, middle and low level assumptions for these projections and for the most recent set of national projections.

## FERTILITY ASSUMPTIONS

Two different measures of fertility are presented here: the Total Fertility Rate (TFR) and Age Specific Fertility Rates (ASFR). The Total Fertility Rate (TFR) is defined as the number of children a woman would bear during her reproductive lifetime if she had children at the current pattern of age-specific fertility rates throughout all of her childbearing years.

Fertility is projected to run parallel to that projected by the U.S. Census Bureau for the U.S. as a whole. No convergence with national trends is predicted by 2050. Fertility in the middle series is assumed to reach an ultimate completed cohort fertility of 2.4 births per woman. For the low and high assumptions, levels of 2.1 and 2.9 births per women were chosen.

While recent national levels of fertility have been declining, Alaska retains the highest fertility level of any state. This trend is projected to continue. Trends in Total Fertility Rates (TFR) for Alaska and the U.S. are shown in figure 1.1 and tables 1.2 and 1.3.

Trends towards increased labor force participation and educational attainment, and a higher age at first marriage have not prevented Alaska from having a resurgence of fertility since the mid 1970s. The reasons for Alaska's higher fertility are not readily apparent. In part, the total fertility is influenced by exceptionally high fertility among Alaska Natives. However, fertility levels are also well above the national average for white women as well. Alaska's higher income should tend to encourage higher fertility and its high level of education should tend to depress fertility. While the reasons for our higher levels of fertility needs further investigation, it is possible that values towards larger average family size may be characteristic of the "frontier" and those who have chosen to live on it.

Alaska's current fertility rate of 2.4 means that the average completed family size for Alaskan families would be 2.4 children per family if the current pattern of childbearing were to continue. Nationally, the total fertility rate is about 1.8 children per family. Zero population growth would be achieved by maintaining a total fertility rate of 2.1 for a period of years. The nation as a whole is projected to fall below zero population growth by 2034. After that time, any growth in the U.S. population is expected to come from migration from abroad. For the purposes of our projections, we, like the U.S. Census Bureau, assume that the relationship of Alaska fertility to the national fertility will remain proportional in future decades to national trends.

In developing the national high, middle, and low fertility assumptions, the Census Bureau has used the following rationale. The major reason for establishing the middle series nationwide at 1,900 births per 1,000 women is based upon a number of current trends:

The birth expectations of women aged 18 to 24 years have been well below 2.1 births per women since the mid-1970s and there are no signs of a rise in these expectations for the foreseeable future. There has been a long term trend toward an increasing number of women entering the work force. Female age at first marriage has been raising as have the occurrence of divorce, the proportion remaining single, and the proportion remaining childless. The average level of education has also continued to raise. It has been shown that womens expectations of future fertility are rarely fulfilled at a later date if they are interupted or delayed. All of these factors contribute to lower levels of fertility and are likely to contribute to further declines unless there is a reversal in some of these social trends.

Nationally ,the "lowest series" ultimately assumes a completed family size of 1.6 children per women. This lower limit is based upon the reluctance of women in the almost all western societies to say they want fewer than two children. The U.S. "high series" fertility assumption is 2.3 births per women. On a national level, evidence suggests that although this level is lower than actual fertility at almost any time in our past, it seems unlikely that the nation as a whole will in the future reach current Alaska levels of fertility.

Migrants are assumed to immediately begin bearing children at the same rate as the equivalent age-race group in the Alaska population. In the absence of vital statistics information on recent migrants, no information is available on any differences in the fertility behavior of the migrant population.

It is important to remember that differences in the fertility series have no effect on the size of the cohorts born before July 1, 1985. Changes in mortality and migration on the other hand impact on every age group. As a result, different fertility assumptions will only affect the population under 6 and the total population.

### Fertility Trends

In the middle series, the number of births would remain at about their current level through the projection period. Thus the births for 1985 were 12,677 and in the middle series are projected to be 13,093 by 1991, an increase of up to 400 a year statewide. The impact of a net loss of migrants in the worst case would only reduce the number of births to 11,400 a year by 1991, while the high level series would increase the births to 14,500 by the same year. After the early 1990's, the number of women in the key childbearing ages is no longer growing as rapidly, thus the future number of births is not expected to grow as rapidly as it has over the last 30 years.

## MORTALITY ASSUMPTIONS

Assumptions regarding future mortality were developed using new Alaska state life tables for 1977-83. These were prepared by the Alaska Department of Labor using the same techniques employed by the National Center for Health Statistics (NCHS) in creating the 1969-71 state life tables.[2] Alaska Births and Deaths for 1977-83 were used in the construction of the life tables for all age groups up to 85. National mortality rates for ages 85 and over were used because the number of deaths at the state level in the upper ages is too small to be reliable.

Recent state life tables for Alaska have also been prepared by the National Center for Health Statistics for 1979-81 (op. cit.). These tables, however, are for only the total population and whites. Comparisons

[2] *Alaska Life Tables for 1977-83*, Demographic Report No. 1, Alaska Department of Labor, Research and Analysis, 1986.

with those prepared by our office show that for almost all ages, our life tables are within standard error of those prepared by NCHS. The main difference is that ours contain life tables for Alaska Natives. To the best of our knowledge, these are the first such tables developed for Alaska Natives.

In projecting mortality, it is assumed that mortality for Alaska will converge to the national average by 2050. National mortality rates reflect those developed by the Census Bureau for its national population projections. According to these projections, by 2050 race differences in mortality are assumed to disappear but sex differences will still remain. Comparisons of the achieved level of life expectancy for both the U.S. and Alaska are shown in Table 1.1.

Mortality is projected to decline under all three assumptions. The middle assumption is consistent with projections done by the Social Security Administration in which rapid declines in mortality rates are projected to the year 2005. The high mortality assumption projects faster declines in mortality with total life expectancy reaching 72.2 for men and 80.1 for women by 2005. Under the low mortality assumption, life expectancy increases to 73.9 for men and 82.0 years for women by 2005. The middle series assumed an increase in life expectancy from 68.8 for Alaska males in 1980 to 72.2 by 2005 and an increase in life expectancy from 76.5 years for Alaska Females in 1980 to 80.1 by 2005.

Life expectancy at birth in the middle series is projected to increase from 74.3 years in 1982 to 76.7 years in 2000. Alaska's life expectancy is below that of the U.S. as a whole. Alaska male life expectancy is assumed to increase from 68.8 years in 1980 to 72.2 years in 2005. Females, who can expect to live 76.5 years under current conditions, are projected to attain a life expectancy of 80.1 years in 2005. Use of the low mortality assumption generates life expectancies about 2 years higher in 2005. Life expectancy at birth under the high mortality assumption is a similar amount below the middle series in 2000.

Since there is no vital statistics information for migrants, they are assumed to be immediately subject to the mortality risks of the appropriate age-sex-race group in the Alaska population.

Table 1.4 shows the trends in life expectancy for the U.S. and Alaska since 1950. Overall changes in mortality play only a minor role in the projections for Alaska.

In Alaska the difference between male and female life expectancy is wider than for the U.S. as a whole. In 1970 the difference was 7.9 years. By 1980, this difference had decreased to 7.7 years. Nationally, the difference between males and females in 1970 was 7.7 years. In 1980,

the U.S. difference between males and females stood at 7.5 years.

Nationally, life expectancy at birth has increased substantially since 1950. White males have gained 4.8 years and white females have gained 4.0 years during this 30 years. Males of other races have gained 4.2 years and females of other races have gained 7.3 years of average life expectancy during this period. While the gap between whites and other races in terms of life expectancy has closed somewhat, average life expectancy for other races still lags behind that of whites. For example, in 1950 other males could expect to live an average of 7.4 years less than white males at birth. Similarly, other females could expect 9.3 fewer years of life at birth than white females. Much of these differences are attributable to higher death rates among other races at specific ages (ie. higher infant mortality). By 1980, however, the gap between white and other races in terms of life expectancy had decreased. This gap has decreased for women faster than for men. Thus, in 1980, other males could expect to live on average 5.4 years less than their white counterparts. Life expectancy of Alaska Natives in 1980 cannot be compared to an earlier time period because of the lack of life tables for earlier years. Life expectancy for Alaska Natives clearly lags substantially behind that of whites and even other races on a national level. Currently Alaska Natives have a life expectancy comparable to that of other races on a national basis in 1970.

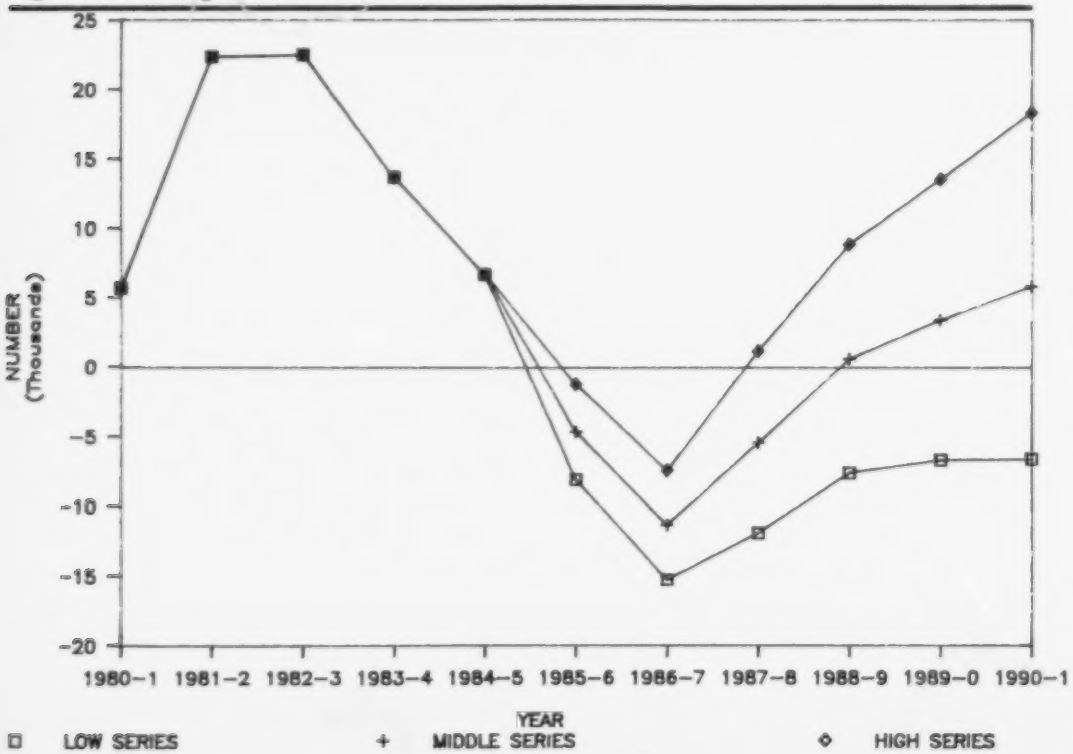
## MIGRATION ASSUMPTIONS

"Net" migration, usually obtained as a residual value, has been the maintstay of projections for many years. This has recently begun to change with the availability of new origin/destination specific migration data in the form of state-to-state and county-to-county migration statistics. These are derived from the Place of Residence Five Years Ago, and Place of Birth questions from the U.S. Census, Internal Revenue state-to-state and county-to-county annual migration flows, and Current Population Survey questions on migration. These data series begin to allow the independent tracking of out-migration from Alaska and out-migration from the balance of the U.S. to Alaska. For these projections, out-migration from the balance of the U.S. includes international immigrants to the U.S. who settle in Alaska. Since each flow is subject to different trends, net migration produces a complex pattern which could almost never be accurately trended.

The assumptions used to achieve levels for migration in these projections involve a separate analysis of migration to and from Alaska. The levels of migration chosen represent a combination of recent trends in migration to and from the state, as well as an evaluation of historic levels of in and out migration consistent with a range of economic conditions. The end result is to produce three series of net migration, roughly equal to the range of probable conditions which may potentially occur during the next five years in Alaska. These trends are shown in figure 1.2 and levels of migration are shown in table 1.5

The middle level migration scenario assumes a slight rise in migration from Alaska in 1985-86 and a continuation of the decline in migration to Alaska begun in 1982, through the 1986-97 period, followed by a gradual return to migration levels comparable to those experienced during 1981 *or* 1985 when there was an average annual rate of growth of about 3.3%. While this projection would show

**Figure 1.2 Net Migration for Alaska 1980-81 to 1990-91**



a net loss of migrants in 1985-86, 1986-87, and 1987-88, only in 1986-87 would the loss be substantial enough to outstrip natural increase and produce a decline in the state's population. This scenario represents a "bust" followed by a return to conditions similar to those which occurred from the late 1960s and early 1970s prior to pipeline construction.

The low series assumes that the current trends in migration to and from the state continue into 1987 and that a period of economic hardship continues through 1991, producing a continued net loss of migrants through the entire projection period. While this is a possibility, it seems unlikely that the current downturn would continue for that period of time. The impact of the worse case would be to hold the state's population at approximately its current level through 1991. In its extreme this represents a long term "bust" scenario. There is no example of this extreme a net loss of migrants in Alaska since World War II, and it seems unlikely that this extreme will be met or exceeded during the next five years.

The high series assumes an optimistic case. It assumes the current trend in migration through 1987 followed by a more rapid recovery by 1989 and a return to positive economic conditions by 1990-91 achieved through a return of oil or a combination of other sectors to levels seen in about 1984. This case represents a short term bust followed by a return to moderate "boom" conditions. The conditions needed for this scenario assume that the decline in oil is a temporary phenomena and/or that another major project or combination of state, national or international economic conditions will cause a return to moderate economic growth in the state.

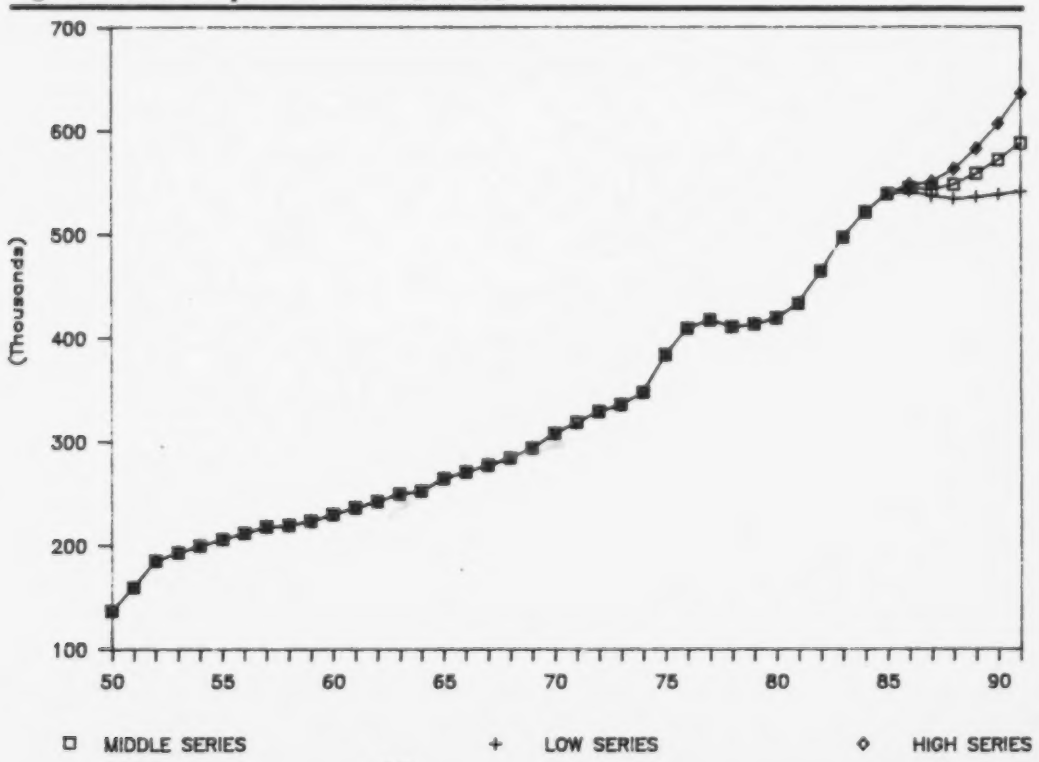
A wide range between the high and low assumptions of net migration is assumed given the uncertainty as to the future course of the price of oil. These assumptions have been chosen in part because of the wide range of possible outcomes in the near term and in part to show what the demographic impact of these extremes would be for planning purposes. It is our belief that it is unlikely that conditions will be better or worse than the extremes set forth here. The future trends in the age groups as discussed below, therefore, are not likely to be outside the bounds suggested.

It is clear that changes in net migration have a much bigger effect on the population than variations in mortality or fertility. There are six times as many births as deaths currently in Alaska and at least four times as many persons moving into or out of the state as are being born.

## PROJECTED POPULATION TRENDS

The recent history of Alaska has been one of tremendous growth as shown in table 1.5 and figures 1.3, 1.4, and 1.5. The population of Alaska in 1986 is almost four times what it was in 1950, just 36 years ago. Anchorage alone is currently almost twice as large as Alaska was around 1950. Natural increase in that time period has been equal to about 57% of the population increase. Major increases due to migration have occurred in three major periods. The first was 1951-1952, the second was in 1975-76 and the third was 1982-1984. There was additionally a minor period of moderate in-migration in about 1970. Historically, there were net losses of migrants in 1978-80, 1956-59 and 1964. The periods in between showed growth due to migration of under 1% per

**Figure 1.3 Alaska Population Growth 1950-1991**



year. Typical growth due to natural increase has been on the order of 1.7-2.3%.

In only 10 of the last 36 years has the average annual rate of growth been over 4%. During 17 of the last 36 years, the average annual rate of increase has been under 3%. Thus the current slowdown in growth is not at all out of character with the post World War II period as a whole. It should also be remembered that the larger the population, the less impact a given "boom" or "bust" has upon it. It is worth noting that the average annual rate of change in the population of the U.S. as a whole has been under 2% for the whole period since 1950 and under 1% since 1980 and the decline in the rate of growth is projected to continue.

In the middle series, Alaska's population would increase from 539,600 persons in 1985 to 588,300 in 1991 (figure 1.4, table 1.5). Most of this growth would occur after 1989. During the 1986-1988 period, population growth in the middle series would be less rapid than it has been in the past (under 1% per year with a small loss in 1987). The U.S. rate of growth during the 1980s has been and is projected to be about 0.92 percent per year.

In the low series population would decline from a high of 542,200 in 1986 to low of 535,000 in 1988 and increase again to 541,800 by 1991. In the high series the population would reach 563,100 by 1988 and then increase to 636,700 by 1991. Even in the high series, however, the average annual rate of growth does not reach 5% by 1991.

Information on the population growth, the average annual rate of change, natural increase, and net and gross migration for the lowest, middle and highest series is shown in table 1.5; and population growth trends appear in figures 1.3 and 1.4. Comparative average annual percent change for five year periods for the U.S. and Alaska appears in table 1.6.

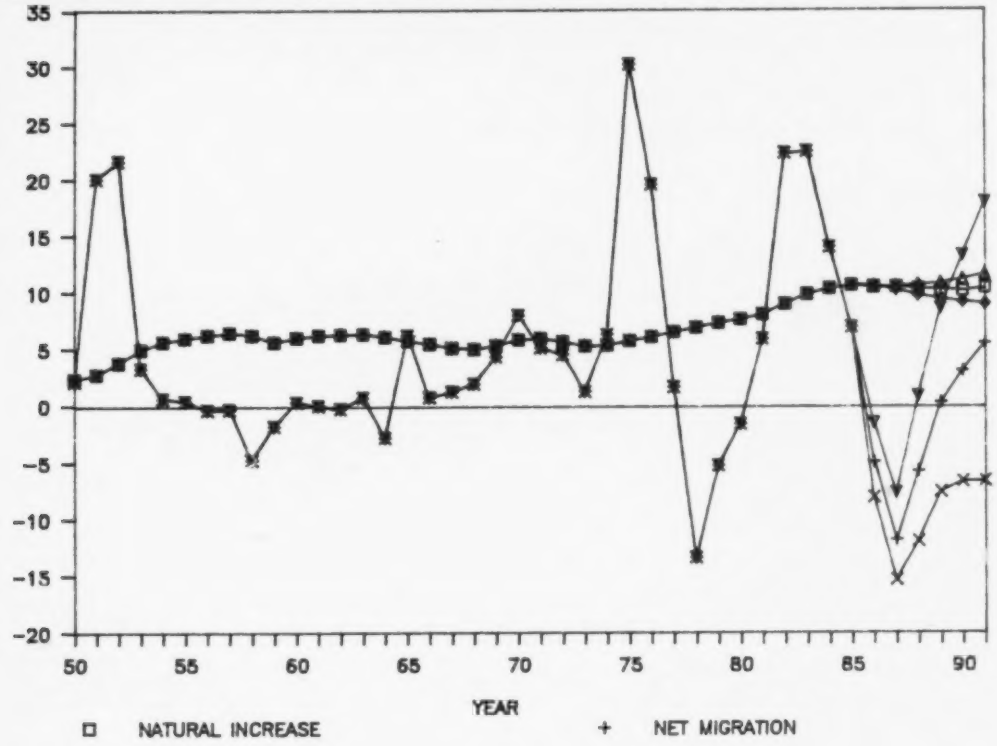

**Figure 1.6**
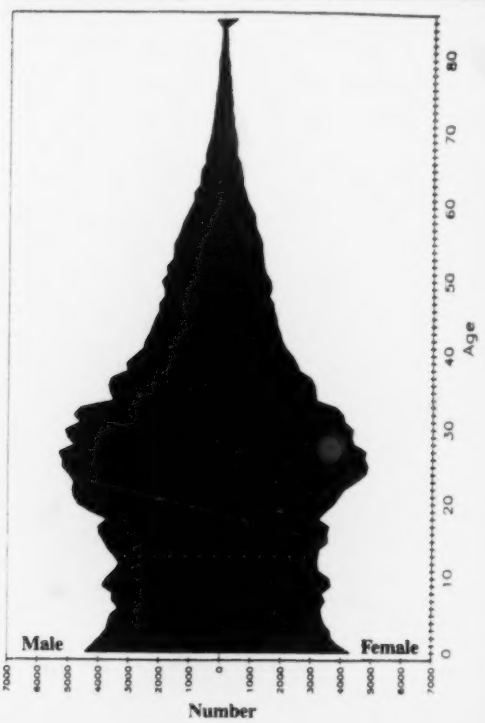
**Alaska Population by Age and Sex, 1980**



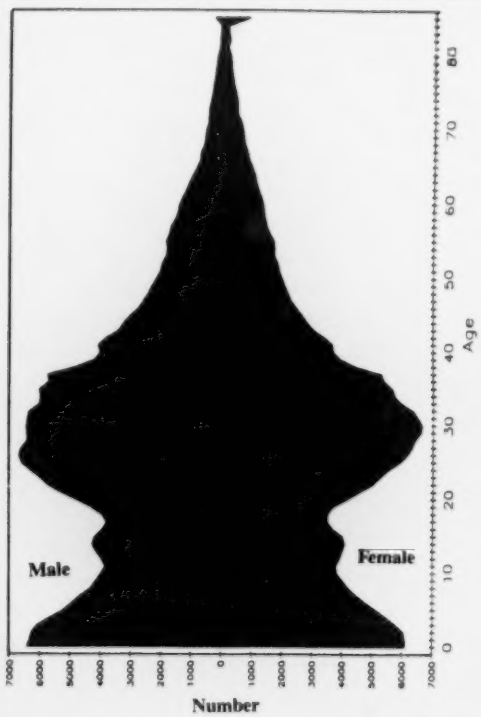
## AGE DISTRIBUTION

### Median Age

A major trend in these projections is the aging of Alaska's population. These trends are shown in table 1.6. For example, in 1980 the median age of the U.S. population was 30.0 years and the average age of Alaska's population was 26.0 years. By 1985, the median age of the U.S. population was expected to be 31.4 years, while Alaska's median age had increased to only 26.6 years. Thus Alaska's population is aging only half as fast as the nation as a whole during the first half of the 1980s. Nationwide the median age in the middle series is expected to reach an average of 33.3 years by 1991, while Alaska's median age in the middle series is expected to increase to 28.6 years. Nationwide the median age will continue to increase to almost 41 by 2030. While we do not project that far with the current set of projections, we expect that the median age of Alaskans, like that of the U.S., will continue to rise into the next century.

One reason for the dramatic increase in median age over the next couple of decades is evident in the population pyramids for 1980 and 1991. (figure 1.6). The 1980 population pyramid still has the character of a very youthful population. By 1991, however, the massive baby boom cohorts will be in their thirties. Currently, about 10 percent of Alaska's population is made up of members of the military and their dependents. This segment of the population will tend to remain younger because of high turnover. Even with the high levels of migration to and from Alaska by the military and young persons in their 20s, the largest bulge of the population continues to age. It will be 40 years before the baby boom cohorts will pass completely through the population. These cohorts should have a stabilizing influence on Alaska's population over that time period, given that an older population tends to be less transient than a younger one.

**Alaska Population by Age and Sex. 1985**



**Alaska Population by Age and Sex, 1991**

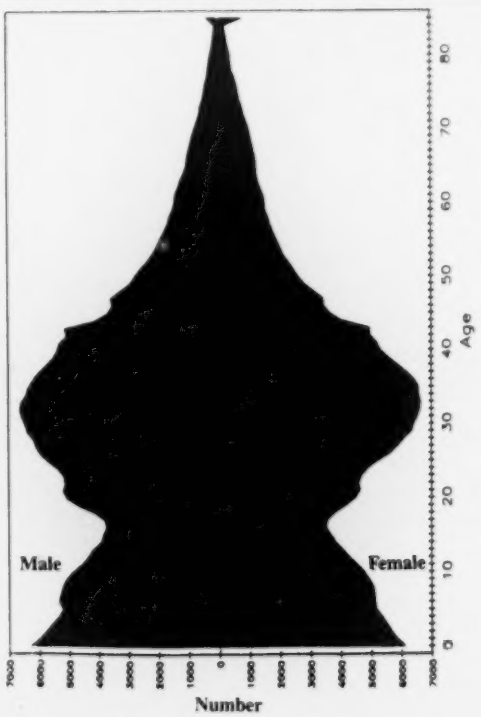


**Figure 1.7 Alaska Population by Selected Groups 1980-91**

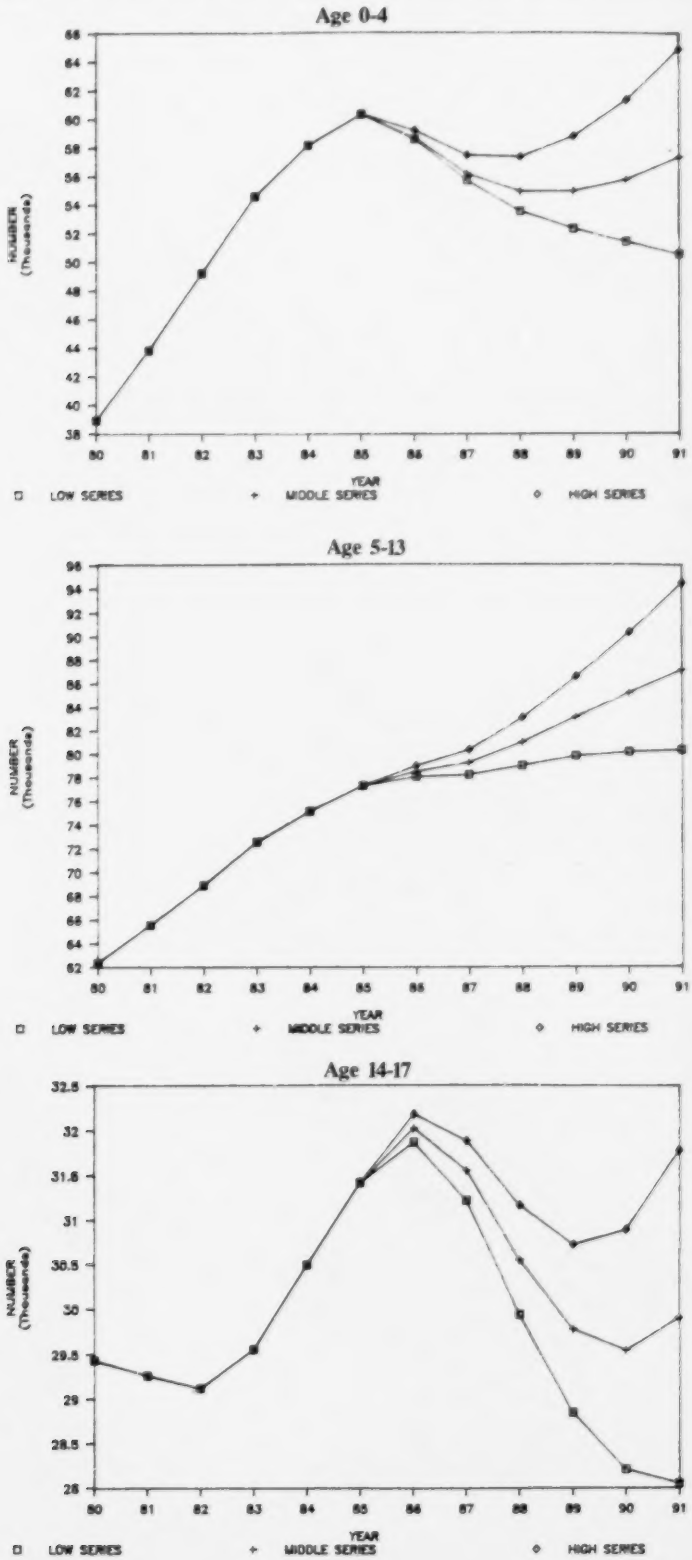
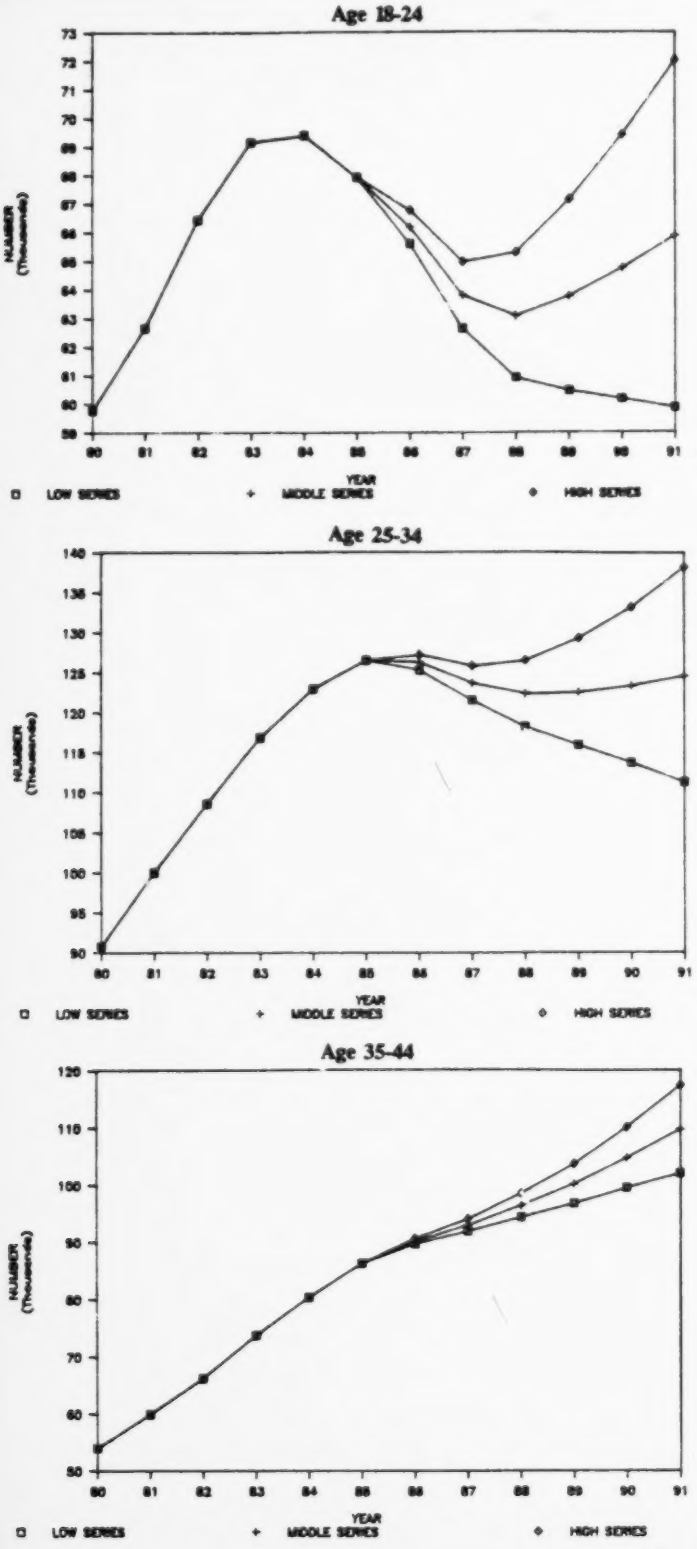


Dependency Ratios.

The changes in the age structure are also reflected in youth and aged dependency ratios. Dependency ratios show the number of children and persons over 65 there would be for every 100 people of working age, those aged 18 to 64 years (Tables 2.1-2.24). Compared to the rest of the United States, Alaska has a high Youth Dependency and a very low Aged Depen-

**Figure 1.7 (Continued)**



dency. In 1980, the U.S. had 46.0 children for every 100 persons of working age, Alaska had 50.4. Similarly, there were 18.6 persons over 65 for every 100 persons of working age in the U.S. as a whole while Alaska had only 4.4. Alaska's total dependency was 54.8 compared to a U.S. Total Dependency of 64.6. By 1991, the U.S. Youth Dependency is expected to drop to 42.0 and the aged dependency is expected to rise to 20.8 for a total dependency of 62.8 persons being supported by every person of working age. In the middle range Alaska projections for 1991, the youth dependency is expected to drop to 45.0, while the aged dependency is expected to reach 6.7, for a total of 51.7. Thus dependency is expected to decline in Alaska more rapidly than in the U.S. as a whole.

Through 2010, the Census Bureau expects changes in the overall dependency ratio to largely reflect changes in the youth dependency ratio. After that time, the elderly dependency ratio is expected to have the most effect on the overall ratio. Nationwide, the dependency ratio of the young population is expected to continue to decline from its present level to 36.2 in 2010, and then stabilize. The elderly dependency ratio of the U.S. is now at an all time high of 19.4. The Census Bureau expects that the U.S. ratio will rise slowly to 21.9 in 2010, and to nearly double its present level by 2030 (37.0). After 2030, the elderly dependency ratio would be larger than the youthful dependency ratio. Although our projections do not extend this far, it is probable that the same trends will occur in Alaska but at a lower level; thus if the same trend continues in Alaska, our aged dependency could also double by 2030.

## TRENDS FOR SELECTED AGE GROUPS

Trends for selected age groups are shown in table 1.7, 1.8 and figure 1.7. The trends for certain age groups are much more volatile than for others in our projections. In particular, the projected population 14-17 and 18-24 are the most volatile and hardest to predict with certainty. The populations over 35 are the most predictable.

The population under age 5 has grown from 38,949 in 1980 to a high of 60,318 in 1985. In the middle series this age group would decline to about 55,000 in 1987 and return to about 57,300 by 1991.

The elementary-school-age population (those aged 5 to 13 years) has risen from 62,363 in 1980 to 77,379 in 1985. This population is expected to increase under the middle range series to 87,163 by 1991. Even under the low series, this age group is expected to be no less than about 80,359 by 1991. Under the high series this age group could grow to as many as 94,500 by 1991.

The high school age group, those aged 14-17 years, was 29,433 in 1980 and declined to 29,120 in 1982. This age group has undergone a particularly rapid increase between 1982 and 1986 when the middle series projects it to reach about 32,000. This age group is projected to decline under all series during the next five years. Under the middle series this age group would shrink to 29,500 by 1990 and rebound to 29,900 by 1991. Under the extremes this age group could range from 28,100 to 31,800 by 1991.

The population aged 18 to 24 years is important to colleges, and in Alaska this age is a key one for military migration and new labor force entrants. This age group contributed substantially to the boom of the early 1980s, growing from 59,773 in 1980 to 67,927 in 1985. Under the middle series, this group is expected to decline to about 63,100 in 1988 before rebounding to about 65,900 by 1991. The range for this age group in 1991 is particularly wide, ranging from 59,900 to 72,000.

The age groups from 25 to 34 years also shows some instability in the next five years. This age group has also grown very rapidly since 1980 from 90,808 to 126,560 in 1985. Under the middle range assumptions this age group is expected to decline slightly, but remain fairly stable through 1991 when the number of persons in this age group is projected to be about 124,700.

The ages 35 to 54 years remain fairly stable through this set of projections. The number of persons in Alaska in these ages has grown substantially since 1980. In 1980 there were 88,265 in these ages. By 1985, the number had increased to 130,023. This group should continue to grow during the next five years at a rate fairly comparable to that experienced in the early 1980s. The middle series projects approximately 166,648 persons in these ages by 1991.

The number of persons 55-64 has also grown rapidly since 1980 from 20,713 in 1980 to 27,839 in 1985. This group is subject to higher rates of migration than the slightly younger ages because it represents an early retirement age. The middle series is expected to grow only to 30,738 by 1991.

The growth of the number of persons over 65 is not expected to be affected substantially in these projections. The number of persons over 65 has increased from 11,547 in 1980 to an estimated 18,133 by 1985. The growth trend of the early 1980s should continue to 1991 when the number of older Alaskans should reach 26,000 according to the middle series. The range for this age group by 1991 should run between 25,400 and 26,700.

## Conclusions

While the next five years are not projected to be the brightest time in the demographic history of Alaska, it is hoped that these projections moderate some of the gloom. At worst, the population of the state is expected to remain stable over the next five years and on average it should continue to grow at a moderate pace. In the most optimistic case, Alaska could return after a short down turn to the kind of growth experienced during its better years. While these projections are statewide in character, we expect the growth to be somewhat differential across the state. In general, we would expect those areas of the state, that experienced the most growth in the early 1980's to be most likely to experience the brunt of the changes in the late 1980s.
